A. The above percent of rejection is for reference only and not to be construed as chemistry, temperature, and TDS are not constant in each water supply.

REVERSE OSMOSIS—HOW DOES IT WORK?

Reverse osmosis (RO) is a separation process that uses pressure to force a solvent through a membrane that retains the solute on one side and allows the pure solvent to pass to the other side. More formally, it is the process of forcing a solvent from a region of high solute concentration through a membrane to a region of low solute concentration by applying a pressure in excess of the osmotic pressure. This is the reverse of the osmosis process,

which is the natural movement of solvent from an area of low solute concentration through a membrane, to an area of high solute concentration when no external pressure is applied. The membrane here is semipermeable, meaning it allows the passage of solvent but not of solute.
